AEP

21 July 2026 09:22

Lesson 1:What is AEP

What is Adobe Experience Platform (AEP)?
Imagine you're the owner of Amazon.
A customer interacts with your business in many ways:

- Visits your website
- Uses your mobile app
- Opens your emails
- Buys products in a physical store
- Talks to customer support

Each system stores its own data.

Without AEP:

→ Website → Database 1

→ Mobile App → Database 2

→ CRM → Database 3

→ Email → Database 4

→ Store → Database 5

Everything is scattered.

Now imagine you want to answer:
"Who is this customer?"
You can't easily, because the information is spread across different systems.

This is where AEP comes in.
AEP collects data from all these sources and combines it into one unified customer profile

Now you have one complete view of the customer.
This is called a 360° Customer Profile.

Lesson 2:Adobe Experience cloud and where AEP Fits

What is Adobe Experience Cloud?
Think of it as a toolbox. Each tool has a specific job, but they all work together.

Product	Purpose
Web SDK	Collects customer data from websites and apps
AEP	Stores and unifies customer data
CJA	Analyzes customer journeys and creates reports
Adobe Analytics	Website and app analytics
Adobe Target	Personalizes content (e.g., showing different banners to different users)
Journey Optimizer	Sends personalized emails, SMS, and push notifications
Adobe Campaign	Manages marketing campaigns

How everything works together

Imagine you visit Amazon.

Step 1: Visit Website
You search for laptops.
👉 Web SDK captures:
Page view
Search term
Product clicks
Cart actions
⬇️
Step 2: Data reaches AEP
AEP stores:
Your name
Email
Device
Location
Products viewed
Purchase history
It creates your Real-Time Customer Profile.
⬇️
Step 3: CJA analyzes
The marketing team can answer:
Which laptops are viewed most?
How many users buy after searching?
Which page causes users to leave?
Which campaign drove the sale?
⬇️
Step 4: Adobe Target
Since you looked at laptops, next time you visit, it shows:
"Get 10% off on laptops!"
⬇️

Step 5: Journey Optimizer
If you left without buying, you might receive:
"Still interested in this laptop? Here's a special offer."
Everything starts with collecting data, then AEP organizes it, and finally other Adobe products use that data.

Lesson 3: Experience Data Model(XDM)

First, what problem does XDM solve?
Imagine you're collecting customer data from three systems.

Website
```
{
  "name": "Mani",
  "email": "mani@gmail.com"
}
```

Mobile App
```
{
  "fullName": "Mani P",
  "mail": "mani@gmail.com"
}
```

CRM
```
{
  "customer_name": "Mani",
  "email_address": "mani@gmail.com"
}
```

See the problem?
All three store the same information, but with different field names.
AEP wouldn't know automatically that:

- name
- fullName
- customer_name

all mean the same thing.
So Adobe created XDM
XDM (Experience Data Model) is a standard format for storing customer data.

Lesson 4: XDM Classes

What is an XDM Class?
Think of a class as a template that tells Adobe:
"What kind of data are you storing?"

Before creating a schema, Adobe asks:
Is this customer information?
Or is this a customer action/event?

That's where XDM Classes come in.
There are two main classes

1 XDM Individual Profile
This stores who the customer is.
Example:
Name: Mani
Email: mani@gmail.com
Phone: 9876543210
Age: 21
City: Bangalore
Notice something?
These are customer attributes. They don't change every second.
Think of it as your Aadhaar card or employee record.
It describes you.

2 XDM ExperienceEvent
This stores what the customer did.
Stores the actions performed by the user
Example:

Visited Homepage
↓
Searched "Laptop"
↓
Clicked Product
↓
Added to Cart
↓
Purchased Product

These are events.
Every click, search, purchase, login, logout, page view, or form submission is an ExperienceEvent.

Why are they separated?
Because:

- Your name doesn't change every minute.
- But your website actions keep happening continuously.
- Adobe stores them separately for better performance and analysis.

How Web SDK uses these

When a customer visits a website:
Web SDK sends an ExperienceEvent like:

```
{
  "eventType": "productView",
  "product": "Nike Shoes",
  "price": 4999
}
```

AEP stores it as an ExperienceEvent.
It then links that event to the customer's Individual Profile using an identity (like email or ECID).
This is how AEP builds a complete picture of the customer.

Lesson 5: XDM Mixins

what is a Mixin?

Imagine you're creating a customer profile.
You already have a class (XDM Individual Profile), but the class only tells Adobe:
"This schema is about a customer."
It doesn't define all the fields like Name, Email, Phone, Address.

That's where Mixins come in.
A Mixin is a reusable collection of related fields that you can add to a schema.

Eg:
Think of buying a new smartphone.

The phone comes with:

- Screen
- Battery
- Processor

Now you add:

- Camera
- Fingerprint Sensor
- Face Unlock

These are like extra features.

Personal Details Mixin

- First Name
- Last Name

- Gender
- Date of Birth

Contact Details Mixin

- Email
- Phone Number
- Address

Loyalty Mixin

- Membership ID
- Reward Points
- Membership Level

Together, your final schema becomes:
Customer
├— Personal Details
├— Contact Details
└— Loyalty Information

Each section comes from a Mixin.

Why not put everything in one class?
If Adobe added everything into one class, it would become huge and messy.
Instead, Adobe lets you choose only the mixins you need.

Types of Mixins

1 Standard Mixins
Created by Adobe.

Examples: Personal Contact Details Work Details Demographic Details

These are ready to use.

2 Custom Mixins
Created by your company.
Example:

Capgemini has a client that sells cars. They create a custom mixin: Car Model Fuel Type Insurance Number Driving License

Adobe doesn't provide these because they're specific to that business

Lesson 6: XDM data types and schemas

What is a Data Type?
A data type is a reusable grp of fields that describe a single object.

Eg: Think about an address.

Instead of creating these fields again and again :

House number Street City State PINCode

Adobe grp them into one address data type.

Now whenever you need an address , you simply use the address data type.

Another Eg: Phone number Country code Phone number Extension

What is Schema?

A Schema is the complete blueprint that defines how your data will be stored in AEP.

It combines:

- Class
- Mixins
- Data type

Into one final structure.

Eg:
If you're creating a customer schema

Step1:
Choose the class: XDM individual Profile

Step2:
Add Mixins: Contact Details,Personal Details,Loyalty Details

Step3: Use Data Types
Eg: House number ,Phone number

What is an XDM Schema?
Answer:
An XDM Schema is the complete data structure in AEP that defines how customer data is organized. It is built using an XDM Class, one or more Mixins, and Data Types, ensuring data is stored in a standardized format.

Lesson 7: Datasets in AEP

A dataset is where the actual data is stored in AEP.

Schema = blueprint
Dataset = storage box

- A schema only defines how data should look
- A dataset actually contains the data.

Can one schema have multiple Datasets??
Yes!
Eg: Custom Schema 1.Website Customers , 2. Mobile app customers , 3.CRM customers

Types of Datasets

1.Profie Dataset

Stores customer profile information.
Eg: Name,email,phone ,city

- Built from XDM individual profile.

2.Event Dataset

Stores customer actions.
Eg: page view,search,product click,purchase

- Built from XDM Experience event.

Lesson 8: Identity Service and Real time customer profile

Identity Service : Is an AEP service that connects different identifiers belonging to same customer and creates one unique identity.

Identity : Value that can identify a customer.
Eg: Email, phone number, customer ID

Identity Namespace tells AEP what type of identity it is

Eg: Email, phone number, customer ID

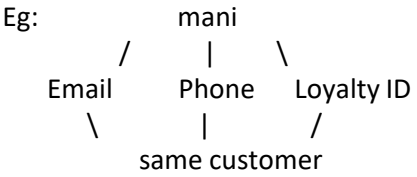

Identity NameSpace: tells AEP what type of identity it is

Eg:

Namespace	Value
Email	mani@gmail.com
Phone	98765432210
CRM ID	C102345

Identity Graph: Network of linked identities is called the identity graph

Eg:

Real-Time Customer Profile:

- a centralized, up-to-the-minute view of an individual customer.
- It merges both known and anonymous data from multiple enterprise sources
- such as CRM, web behavior, and mobile apps
- into a single actionable record

Lesson 9: Data Ingestion In AEP

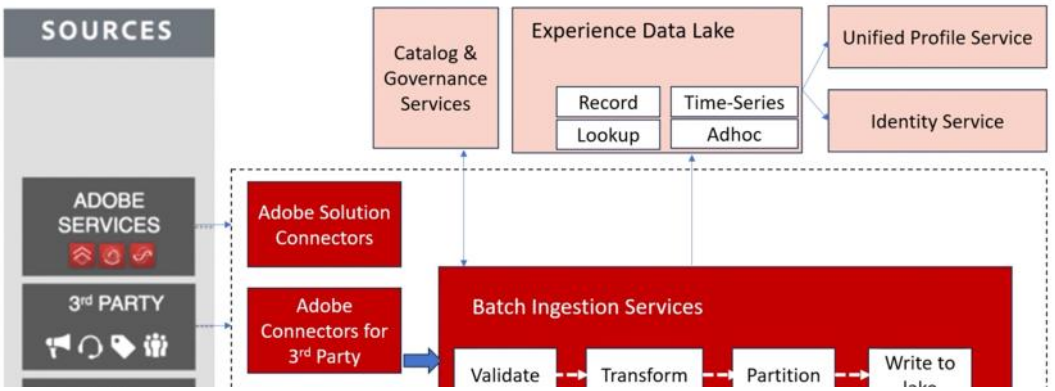

Data ingestion: is the process of bringing data from different sources into AEP.

Data Ingestion in AEP

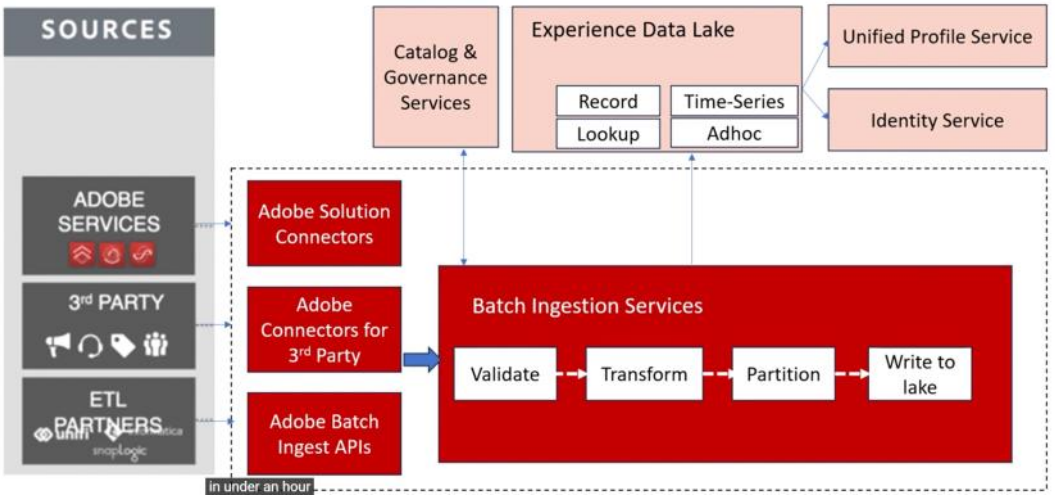

1.Batch Ingestion

2.Stream Ingestion

1 **Batch Ingestion**

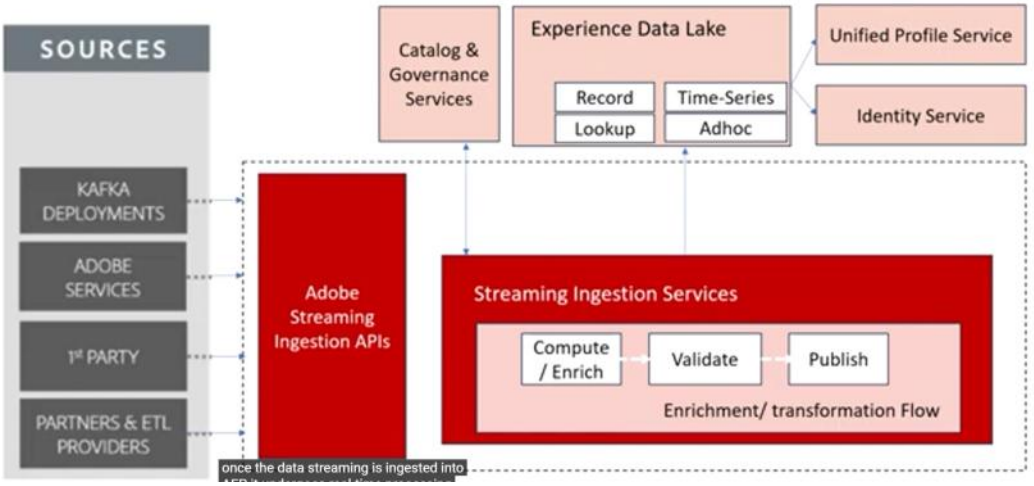

1 **Batch Ingestion**

- It lets users send file data at schedule intervals to AEP in a performance manner
- Customers can upload up to 100GB of data historical or offline at once and data is made available in the data lake in under an hour
- Data uploaded via block ingestion is consumed by profile and identity as soon as data is available in data lake

2.

Streaming Ingestion

- It lets users send data to EP in real time from client and server side devices.
- A line for immediate insights and actionable intelligence allows updates to real time customer profiles at sub second latency.
- Once data is ingested ,it undergoes real time processing and enrichment and once data is validated it is published go data lake.
